

Encryption

COMP620 Information Privacy
& Security

Cryptography

- Cryptography in general represents the process of encrypting a plain-text file into an unreadable cipher so that it can be stored and decrypted by the intended recipient.
- Plaintext can be any bunch of bits, text, graphics, program, etc.

Historical Encoding

- People have been writing secret messages for millennia
- The Caesar cipher (*shift cipher*) is said to have been used by Julius Caesar
- Computational efficiency was very important before computers

Encryption Media

- Encryption can be used to secure information sent over a network.
- Encryption can also be used to secure data stored on a computer.

Caesar or Shift Cipher

- The letters of the alphabet are shifted by a fixed amount
- Key is the number of letters to shift
- Can easily be defeated by trying all 26 possible shifts

Decryption by Brute Force

- Frpsxwhuv duh ixq
- Eqorwvgtu ctg hwp
- Dpnqvufst bsf gvo
- Computers are fun

Types of Attacks

We assume that an adversary knows the encryption algorithm and has:

- **Ciphertext only** – samples of ciphertext without information about the content
- **Known plaintext** – examples of ciphertext and the corresponding plaintext
- **Chosen plaintext** – adversary can get ciphertext samples of plaintext of their choosing

Substitution Cipher

- Letters are mapped to symbols or letters
- Key – An alphabetical list of the symbols

Ɔ	ɔ	Ń	Δ	↳	ŋ	⊕	⊖	↳	⊂	†	⊂	⊂
A	B	C	D	E	F	G	H	I	J	K	L	M
ŋ	⊖	⊕	⊂	4	↳	⊕	⊖	Ÿ	⊕	⊗	Ÿ	⊂
N	O	P	Q	R	S	T	U	V	W	X	Y	Z

- There are $26! = 4 \times 10^{26}$ possible keys

Letter Frequency

The frequency of the use of a letter in English

The frequency of letter pair, triples, and short words are also available on the web.

Cipher Text

What does this say?

Chancellor Martin

Effectiveness of Frequency Decryption

- Sample substitution cipher text was partially decrypted using only the letter frequency.

Guess what it says

Vigenère Cipher

- Originally described by Giovan Battista Bellaso in 1553
- A text key is repeated for the length of plaintext

$$C_i = (P_i + K_i) \bmod 26 \quad \text{to encrypt}$$

$$P_i = (C_i - K_i) \bmod 26 \quad \text{to decrypt}$$

welcometonorthcarolina plaintext
 informationprivacyinfo key
 erqqfyemwbbgkpxatmtvso ciphertext

Vigenère Cryptanalysis

- For long text and short keys, character frequency analysis provides a lot of information
- Sometimes the same plaintext letter will be encrypted by the same key character
- Statistical analysis on the frequency and distance between matches gives an indication of the key size

Running key cipher

- The running key cipher is similar to the Vigenère cipher, but a long, non-repeating key is used.
- Typically the key is some common publication, such as a book or periodical
- Example using well known C book

Plaintext: f l e e a t o n c e w e a r e d i s c o v e r e d
 Running key: E R R O R S C A N O C C U R I N S E V E R A L P L
 Ciphertext: J C V S R L Q N P S Y G U I M Q A W X S M E C T O

One-Time Pad

- With one-time pad encryption, the bit stream of the message is XOR with a random key
- The key must be at least as long as the message so it is not repeated
- The key must be truly random, not just pseudo-random

Perfect Encryption

- One-time pad is a perfect encryption technique that cannot be broken
- A given cipher text can be decrypted into any possible plain text by using the appropriate key

011001010	cipher text
010101010	with key 001100000
000011111	with key 011010101

Running Key Analysis

- If the key text for the running key is perfectly random, then it is the same as one-time pad
- Usually human text is far from random providing relatively poor security
- You can subtract probably plaintext from the cipher text down the whole string and look for readable text, which is probably part of the key.

Diffusion and Confusion

- **Diffusion** – spread the plain text data across the cipher text. A byte of plain text should impact many bytes of cipher text
- **Confusion** – change the bits of the plain text according to some rule

Types of Encryption

- Symmetric Key or Secret Key
 - The encryption key is the same as the decryption key.
 - Sender and receiver have to securely share a key.
- Asymmetric Key or Public Key
 - The key to decrypt is different, but related to, the key to encrypt.
 - The encryption key can be made public while the decryption key is kept secret.

Symmetric Key Cryptography

- Keys exchanged prior to communications. Parties verified at that time.
- Key to encrypt message is the same as key to decrypt.
- DES and AES are examples of Symmetric Key Cryptography.

Why Publish a Standard?

- The Data Encryption Standard (DES) and Advanced Encryption Standard (AES) algorithms are published and well known
- Why not keep the algorithm secret?
- To be useful, others have to implement it.
- A good encryption algorithm will allow only those with a key to access the data. Knowing the algorithm does not give you access.

Asymmetric Key Cryptography

- Public key different from private key.
- RSA encryption is an example of Asymmetric Key Cryptography.

Encryption Performance

- RSA asymmetric key encryption is slower than DES or AES.
- DES and AES are easy to implement in hardware.
- AES can be efficiently implemented in software.
- Hybrid encryption uses both asymmetric and symmetric key systems.

Key Strength

- The longer the key, the harder it is to defeat the encryption by brute force.
- If the key is n bits, it requires 2^n guesses to try all possible keys. You are likely to guess correctly in 2^{n-1} tries.
- Asymmetric key algorithms require a mathematical relation between the keys so not every bit string can be a key.

Key Lengths

- DES uses a 56 bit key
- Triple DES or DES3 uses two DES keys for a total of 112 bits
- AES uses 128, 192 or 256 bit keys.
- RSA uses variable length keys, frequently 512, 1024 or 2K bits in length.

Brute Force Decryption

- Brute force tries all possible keys.
- In 1998 the Electronic Frontier Foundation built a device that could brute-force a DES key in a little more than 2 days

Hybrid Cryptography (STEP 1)

- DES key is encrypted with asymmetric key cryptography using Public Key of receiver.
- DES key sent to receiver.
- Both users end up with a shared DES key.

Hybrid Cryptography (STEP 2)

- Message is encrypted with the DES key previously sent to the receiver.
- DES key is discarded after sending the message.

STEP2
